

Types of Artificial Intelligence

Not every AI is trying to take over the world.

A visual taxonomy of machine cognition.

Why AI Needs a Taxonomy

Systems range from single-task spam filters to highly flexible language models to hypothetical human-level intellects.

Grouping them all as 'AI' obscures reality.

Lens 1: Classification by Capability
How smart is it?

Lens 2: Classification by Functionality
How does it process information?

Do not mix these frameworks. They measure fundamentally different things.

The Capability Lens: Measuring the Scope of Competence

Artificial Narrow Intelligence (Weak AI)

The Reality Line

Designed to perform specific tasks or a limited range of tasks.

Narrow = The Specialist. Almost all AI deployed today falls in this category, regardless of how impressive it seems.

Artificial General Intelligence (AGI)

A hypothetical system with broad, human-level general intelligence capable of cross-domain reasoning.

Artificial Superintelligence (ASI)

A hypothetical intellect that surpasses human intelligence across essentially all important intellectual domains.

Does Not Exist.
Purely conceptual.

The Capability Diagnostic

	Narrow AI	AGI	ASI
The Metaphor	The Specialist	The Generalist	The Superhuman
Scope of Adaptability	20%  Specific / Limited	80%  Broad	100%  Extremely Broad / Beyond Human
Intelligence Level	Specialized	Human-level	Superhuman
Exists Today?	 Yes (Spam filters, Voice assistants)	 Not established	 No

The Function Lens: The Evolution of Machine Cognition

This framework categorizes how an AI processes information and relates to its environment, not merely what tasks it can accomplish.

Current Reality: Algorithms and Memory

Reactive Machines

Responds exclusively to current inputs without maintaining a persistent memory of past experiences. Limited adaptation.

Example: IBM Deep Blue.

Limited Memory

Learns from previous data or recent context to inform current actions.

Examples: Autonomous driving, recommendation engines, language processing.

Note: Training on historical data does not equal “human-like memory.”

The Reality Line

Theory of Mind: Simulating Mental States

A theoretical category where the system understands beliefs, intentions, emotions, and perspectives.

“This person said they’re fine, but their behavioral data suggests they’re upset.”

Open Research Problem.
Not demonstrated in
current AI.

Self-Aware AI: The Consciousness Question

A purely hypothetical category where an AI possesses a self-model and internal subjective experience.

- Requires genuine self-awareness.
- Requires internal subjective experience (qualia).
- Consciousness remains a major scientific and philosophical mystery even in humans.

There is ZERO scientific evidence that any AI system today is conscious or self-aware.

Expectation vs. Technical Reality

Public Perception

Graph 1 (Expectation)

Technical Reality

Graph 2 (Reality)

Narrow / Limited Memory AI

Basic Code

Sentence

The public discourse forces a false binary. Reality exists in the nuanced middle ground of specialized, non-sentient optimization.

The Complete Picture: Plotting Current AI

The illustrated reality box

Even the most remarkably capable language models today are fundamentally *Narrow* and operate on *Limited Memory*. The frameworks overlap, but do not conflate them.

The Taxonomy Checklist: What's Real?

✓	Narrow AI	Specialized Intelligence	(Capability Lens, Cobalt Blue)
✓	Reactive	No persistent memory	(Function Lens, Vermilion)
✓	Limited Memory	Contextual learning	(Function Lens, Vermilion)
----- Current Engineering Limit			
✗	AGI	Human-level generalist	(Capability Lens, Cobalt Blue)
✗	ASI	Superhuman intellect	(Capability Lens, Cobalt Blue)
✗	Theory of Mind	Understands emotion	(Function Lens, Vermilion)
✗	Self-Aware	Conscious experience	(Function Lens, Vermilion)

Almost all AI we use today falls within Narrow AI, regardless of its flexibility.
We are building powerful tools, not minds.
